

# Geotechnical Investigations

Transmission Company Victoria (TCV) are carrying out field surveys across the VNI West draft corridor. This work is important and builds our understanding of environmental considerations such as flora, fauna and the geology of the area.

We will apply the findings along with feedback from landholders and the community to help identify the route for the transmission line that minimises impacts to people, farming and the environment.

## Geotechnical investigation program outline

TCV is continuing a program of geological field studies across the VNI West draft corridor. These assessments are expected to run from March to May this year.

Across the entire draft corridor 27 boreholes will be drilled. Each borehole will be about 100mm in diameter and reach depths of no more than 35 metres.

All geotechnical drilling related field work will take place on public land and all required permits have been obtained from relevant local authorities. Crews will be visible on roadsides as investigations take place. These sites are not indicative of where towers will be located. Once tower sites are determined, further geotechnical bores will need to be undertaken at each of those locations.

## Preliminary Surveys

We are undertaking preliminary survey activities to help us understand the current state of environmental values. TCV has referred the VNI West project to the Victorian Minister for Planning

to determine whether an Environment Effects Statement (EES) will be required.

These preliminary studies are important to help inform the scope of an EES if required by the Minister. The planning and approvals phase of the project will undertake a wider range of environmental and technical studies including cultural and historic heritage, economic benefits, the environment and community considerations.

## Geotechnical investigations in the community

Once sites are identified as suitable for geotechnical drilling, engineering, ecological and cultural heritage specialists assess the area for any potential issues before any survey drilling activities begin.

Geotechnical investigations will take place within a fenced off work zone to ensure field investigations can be completed safely. There will be multiple vehicles at each survey site including traffic management, pumping and drilling equipment.

Rock and soil samples from the drilling activity will be used to assess the broader geological features of the region. The TCV website is regularly updated to inform communities of upcoming survey activity.

## Site remediation for boreholes

Each borehole is remediated directly after drilling activity concludes. Boreholes are backfilled in strict accordance with the Australian Drilling Industry Association's guidelines.

Every borehole is sealed with a cement-based grout with a high-water ratio, forming a solid mass that is soft enough for digging machinery to cut through, should any future works be required in the area by TCV or other public works companies. Bentonite may also be used in the borehole sealing process.

Boreholes are sealed via a pump and tremie line method, the low viscosity grout mixture is pumped below the waterline ensuring all void spaces below ground are filled. The remainder of the borehole is filled with compacted soil from the drilling process. Boreholes are sealed in this way to prevent water seepage and collapse of the borehole.

## Safety and biosecurity

For this program of works, TCV requires Works Within the Road Reserve (WWRR) permits from the relevant shire council prior to contractors commencing surveys. Crews have copies of these permits at each survey site.

Permits for works on shire council road reserves do not specify any biosecurity measures be undertaken.

TCV will enact strict biosecurity procedures within the crown land and private properties, such as vehicle and boot washdowns with common farming disinfectants.
